Miraflores: the return as claims with proof

The workpaper answers four questions about every return value: where did it come from, what changed, who checked it, and what remains open? The starting point is a review queue. Tax schedules are generated views of the same claims and evidence, rather than separate files to keep in sync.

A preparer follows a claim into the printed source, records the exact supporting passage, and verifies or proposes a correction with a reason. Engine, proposed and approved values stay separate. An independent reviewer approves the work; material tax effects require a partner. Evidence changes invalidate the approvals that depended on it. A client answer is evidence to evaluate, never automatic proof.

Data model

Records	Purpose
Packet, document, page, extraction, locator	Preserve the supplied JSON and SHA-256. Locate exact source text; retain manual anchors and document dispositions.
Claim and evidence edge	Identify a line by return version and key. Connect source fields, other claims, prior-year records, client answers and agency evidence in both directions.
Verification, adjustment, decision, review	Record method, evidence, original/proposed value, authority, rationale, contributors and independent approval. Fingerprints bind review to the evidence it covered.
Filing snapshot, submission, amendment	Freeze a hashed, database-protected copy per attempt. Preserve rejected copies; link resubmissions and amendments to their predecessors.
Policy, assignment, time entry, audit event	Version firm rules, track responsibilities/budgets and retain who changed or viewed what. Operational retention changes do not invalidate tax review.

PostgreSQL holds these records and transactions. Expected revisions prevent one editor from silently overwriting another. Files are private attachments behind the same authorization boundary; local files serve development and an S3-compatible adapter serves deployment.

Readiness and honest limits

Readiness is computed from current proofs, document/area coverage, outside responsibilities, blocking notes, required steps, staff sign-offs and both clients' authorization of the exact draft. Nothing is marked complete merely because it was extracted confidently.

This prototype is not a tax engine. A small checked formula registry recomputes arithmetic. Other affected lines retain an explicit basis label, and tax effects use the packet's rates as estimates. Simulated filing requires a partner to accept that limitation. Frozen copies retain the calculation basis and supporting record; later quality findings never rewrite them.
